1	Why even reproduce?	1
2	Do organisms create exact copies of each other?	1

1 Why even reproduce?

After all, reproduction is not necessary to maintain the life of an individual organisms, unlike Respiration etc. And creating a new individual, would take a lot of effort and energy. Why go through this trouble?

If a species doesn't reproduce it won't be able to survive and will go extinct. If a species had a only one individual and it doesn't reproduce, we would never notice it.

Wait, I have a question

How do we know that two different individual organisms belong to the same species? 

Usually, we say this because they look similar to each other. Thus, reproducing organisms create new individuals that look very much like themselves.

2 Do organisms create exact copies of each other?

Reproduction at its most basic level will involve making copies of the blueprints of body design.

Chromosomes in the nucleus of a cell contain information for inheritance of features from parents to next generation in the form of DNA (Deoxyribo Nucleic Acid) molecules.

The DNA in the cell nucleus is the information source for making proteins. If DNA(information) is changed, proteins will change. These different proteins will lead to altered body designs.

So the most basic event in reproduction is the creation of a DNA copy. Cells use various chemical reactions to replicate the DNA. But simply creating this copy and pushing it out won't help, because it won't have the supporting cellular apparatus. Therefore, DNA copying is accompanied by the creation of an additional cellular apparatus, and then the DNA copies separate, each with its own cellular apparatus. Effectively, a cell divides to give rise to two cells.

These two cells are of course similar, but are they likely to be absolutely identical?  The answer to this question will depend on how accurately the copying reactions involved occur. No bio-chemical reaction is absolutely reliable. Therefore, it is only to be expected that the process of copying the DNA will have some variations each time. And because of this, the copied DNA is similar but identical to the original DNA. Some of these DNA variations may be so drastic that the organism just dies because the cellular organelles are not able to work with DNA.

Here is the cool part, there may be some variations which are not drastic and hence these variations stay on and only these types of variations go to the next generation.

and this leads to EVOLUTION!
